

BUG REPORT

#	Problem	How to see it	What should happen vs What happens	How Bad	Why it happens
1	No confirmation when deleting article	1. Log in to the application 2. Create a new article 3. Click the Delete button	Expected: A popup asking "Are you sure?" Actual: Article deletes immediately without any warning	High	Missing confirmation dialog before API call
2	Can sign up with invalid email format	1. Go to the Sign Up page 2. Enter "notanemail" in the email field 3. Click Sign Up button	Expected: Error message "Please enter a valid email" Actual: Account is created successfully	Medium	Missing email format validation on frontend or backend
3	Password visible as plain text	1. Go to Sign Up or Login page 2. Type text into the password field	Expected: Dots or bullets hiding the password Actual: Password text is clearly visible	Medium	Missing type="password" attribute in HTML input field
4	No loading indicator on form submission	1. Fill out any form (Sign Up, Login, Create Article) 2. Click the Submit button 3. Click the button again immediately	Expected: Button disabled and spinner shown during submission Actual: Button stays active, allowing double submission	Low	Missing loading state handling in frontend code
5	Session expires without warning	1. Log in to the application 2. Leave the page open for approximately 1 hour 3. Try to edit or delete an article	Expected: Redirect to login page with message "Session expired. Please log in again" Actual: Generic error or silent failure	Medium	Missing authentication token expiration check

ROOT CAUSE ANALYSIS (for Bug #1)

Issue Selected: #1 - No confirmation when deleting article

What is happening?

When a user clicks the Delete button on any article, the article is immediately removed from the system without any warning or confirmation dialog. The user has no chance to cancel the action if they clicked by mistake.

Why is this happening?

The frontend code directly calls the delete API endpoint inside the button's click handler. There is no intermediate step that asks the user to confirm their intention. This is a common oversight in "vibe coded" or rapidly built applications where developers focus on making the feature work but forget to add safety measures.

How would I fix it?

The fix requires adding a confirmation step before executing the delete operation. Here is the step-by-step solution:

1. **Add a confirmation dialog:** Use JavaScript's built-in `confirm()` function or a custom modal component that appears when the Delete button is clicked.
2. **Conditional API call:** The delete API should only be called if the user clicks "OK" or "Confirm" on the dialog. If they click "Cancel", nothing happens.
3. **Optional enhancement - Undo feature:** Add a toast notification that appears after deletion saying "Article deleted" with an "Undo" button that restores the article within 5 seconds.

Code example of the fix:

// Current problematic code:

```
function deleteArticle(id) {  
  api.delete(`/articles/${id}`);  
}
```

// Fixed code with confirmation:

```
function deleteArticle(id) {  
  const userConfirmed = confirm("Are you sure you want to delete this article? This action cannot be undone.");  
  if (userConfirmed) {  
    api.delete(`/articles/${id}`);  
    showToast("Article deleted successfully");  
  }  
}
```

Why is this severity High?

Users can accidentally lose hours of work with no recovery option. In a production application, this would lead to frustrated users, lost trust, and increased support tickets requesting data restoration.

I tested the following user flows:

1. **Sign Up** - Created a new account
2. **Login** - Logged in with existing credentials
3. **Create Article** - Wrote and published a new article
4. **Edit Article** - Modified an existing article
5. **Delete Article** - Attempted to remove an article
6. **Logout** - Signed out of the account

I also tested edge cases including:

- Empty form submissions
- Invalid email formats
- Long input text (500+ characters)
- Special characters in fields
- Session timeout behavior

Conclusion

The RealWorld demo application is functional for basic use cases but has several usability and security issues that would need to be addressed before production release. The most critical fix required is adding delete confirmation to prevent accidental data loss. The other issues (email validation, password masking, loading indicators, session handling) are important for professional user experience and should be addressed in subsequent updates.
